NEW ALA1530LNPro Imperium
HIGH GAIN MAGNETIC BROADBAND
ACTIVE LOOP ANTENNA

50kHz to 30MHz
New Ultra low Noise Figure JFET Design
with an 8dB gain boost above 10MHz

The ALA1530LNP is the high gain version of the ALA1530LN. This compact Active Magnetic loop antenna primarily designed to provide improved performance over conventional passive and active antennas. This antenna together with the ALA1530LN are the only 1m dia. loops in production to use an ultra low noise JFET design. The loop has had a significant design change to improve LW/MW and SW reception. The antenna gain is increase by 9dB and the LW and MW signal to noise ratio s/n is up to 10dB higher, with an improved s/n and gain on the HF bands. The LW and MW 3rd order IMD is now approx. 20dB lower. This being a combination of altering the gain distribution the lower IMD of the JFETs. Over the last 20 years the ALA1530 range of loops has redefined the active antenna market place; by affording the user the possibility to reject locally radiated and mains borne noise and still provide improved sensitivity compared to larger antennas. 1m dia. Aluminium loop is designed for outdoors, even at ground level. The loop has a frequency range from 50kHz to 30MHz and matches directly to the receiver. The ALA1530 series have become the premiere active loop antennas for the Radio Enthusiast, Government Monitoring and Broadcast organisations.

The amplifier is fitted in a separate module to reduce mechanical stress and facilitate easy replacement. The base of the loop is now reinforced with an acetal rod to minimised damage due to weather extremities.

The new ALA1530LNP is the second generation of this antenna and uses 8 very high gain JFETs in parallel push-pull with a Bipolar transistor cascode stage for extended bandwidth. Optimum noise-less transformer feed-back resulting in a ultra low noise figure.

- Balanced low impedance Magnetic loop with enhanced performance compared to shielded and Moebius loop types
- Ultra low noise JFET design with up to 13dB lower noise floor compared to conventional low noise and MMIC amplifiers
- Unique two transformer Norton amplifier with a +55dBm IOP3 ensures good performance in a strong signal environment
- Up to 30dB rejection of locally radiated and power-line noise compared to an active whip
- Figure of eight directivity and deep nulls to further reduce interference; Ideal for LW/MW with antenna rotator
- Very low intermodulation, up to 40dB lower 3rd order IMD compared to loops using MMIC devices
- Rugged construction 1m dia, Aluminium loop, with Antenna Interface and a regulated power supply for most countries
- No tuning necessary or matching unit; No planning problems, works at ground level, can be camouflaged
- Separate Head Amplifier fits on top of loop to reduce mechanical stress and afford easy replacement.

**This is no ordinary loop antenna**

The ALA1530LNP is the result of several years development spun off the design of the large aperture loop, the ALA100LN. Most Broadband loops work by a current induced by the H or Magnetic Field increases with a rising frequency to negate losses with the loops inductance. Hence, the loop tends to have a flat sensitivity versus frequency. Loop antennas are usually designed by connecting a low impedance, high gain amplifier to a single or multi-turn loop (shielded). This approach presents several problems:

1. Shielded Moebius and Multi-turn loops have too much capacitance or inductance and hence reduced HF bandwidth. A Moebius shielded loop has 4-5 x the inductance of the ALA1530LNP loop thus limiting the loop current with 6-12dB roll off above 20MHz
2. Optimum loop/amplifier power transfer occurs over a narrow bandwidth. Also the loops radiation resistance is very small, meaning that it picks up little signal and hence requires an extremely low noise, high gain amplifier to provide optimum reception.
Wellbrook has solved the above problems by designing an amplifier so that the very low noise of the loops real resistance is mismatched to the input impedance of the low noise amplifier. Hence, reducing the amplifier noise floor by up to 13dB compared to more conventional low noise and MMIC amplifiers. This can only be done with JFET amplifiers with a near to zero noise figure.

The E-Field is cancelled out by virtue of the loop aperture being very small in terms of wavelength and the phase difference of the balanced loop output is 180 degrees.

**MAGNETIC LOOP ANTENNA ADVANTAGE**

Most active antennas are the whip type and respond mainly to the electric-field. The Magnetic Broadband Loop responds primarily to the magnetic-field, this ensures high rejection of nearby electric-fields. The intensity of the electric-field is usually higher than the magnetic-field when an antenna is close to interference sources such as TVs, florescent lamps, mains wiring etc. Therefore, by rejecting the electric-field there will be a reduction in local interference compared to other types of active and passive antennas. Interference reduction is further enhanced by the deep nulls of the 'Figure-of-Eight' directivity pattern.

**INTERMODULATION**

Some active antennas generate intermodulation products which can appear as spurious signals interfering with reception. This interference is usually second order intermodulation is caused by non-linearity in the amplifier, producing signals which are the sum and difference of strong Broadcast stations. The ALA1530LNP Broadband Loop has been specifically designed to reduce intermodulation products to a minimum. The second order and the third order intercept points are typically +90dBm OIP2 and +55dBm OIP3 respectively. Thus the level of the intermodulation products are generally below the atmospheric and man made noise.

**ANTENNA DESIGN**

The Loop antenna consists of a rigid aluminium loop and uses 8 very high gain JFETs in parallel push-pull with a Bipolar transistor cascode stage for extended bandwidth. Optimum noise-less transformer feed-back dynamically drives the JFET source resistance to a fraction of an Ohm, resulting in a ultra low noise figure. The amplifier is encapsulated in resin and housed in a uPVC box, this ensures reliable operation in all weather conditions. The antenna provides low noise performance, large signal handling ability. Rejection of mains borne noise is accomplished by using a balanced amplifier so that the feeder does not form part of the antenna return path. The amplifier input is protected with high speed diodes.

The ALA1530LNP is supplied with a Antenna Interface using unique two transformer Norton 9dB amplifier and a 12 volt regulated power supply. RG58C 50 ohm coaxial feeder cable is recommended for the antenna. The recommended maximum feeder length is 100m. A 1m coax. lead connects the Antenna Interface to the receiver. To realise the benefit of the improved s/n, the ambient local noise needs to be low too.

The ALA1530LNP should be positioned approximately 5m away from any buildings.

**TECHNICAL INFORMATION**

- **Power consumption:** 12 volts at 200mA
- **Amplifier Intercept point typically (MW Band):** OIP2 +90dBm, OIP3 +55dBm
- **Amplifier Noise Figure:** Approx. 0.2dB
- **Output impedance:** 50 ohms BNC
- **Max. Field strength:** 400V/m or 1.0A/m pulse
